Can Case Studies Be Used to Teach Critical Thinking?

Clyde Freeman Herreid

Everyone says they want to teach critical thinking. I have seen these words used as talismans on untold numbers of grant proposals. It falls from the lips of curriculum reformers of every stripe. It has to be the number one phrase David Letterman would put at his top 10 list of clichés of grant entrepreneurs. It is the equivalent of the Holy Grail for educators—not necessarily teachers, but “educators.”

Yet average professors don’t appear to give a hoot about the term. They are content to go into the classroom and get on with the job of ripping through their lectures so they can get back to their labs and do the university’s real work—research—which ideally will bring fame and fortune to themselves and their universities.

Like many of us, I have given a lot of thought to the use of the term critical thinking. Just what does it mean? There are whole books written on the subject, and they haven’t helped me one bit. Except to make me feel guilty that I may not be putting enough emphasis on critical thinking in my classroom—even if I don’t know what it is.

Let me think out loud here for a minute. Critical thinking can’t be just the content of a discipline, can it? It sounds more important than that. Yet, certainly, content must be involved; otherwise, one can’t really think about a subject about which he knows nothing. But then, how would that explain my daughter, who was a television reporter and often knew little about the subject she was covering? She had an uncanny ability to ask great questions and to pull information out of even the most irascible academician. But then, how would that explain my daughter, who was a television reporter and often knew little about the subject she was covering? She had an uncanny ability to ask great questions and to pull information out of even the most irascible academician. But still, content knowledge must be somewhere. If this is true then, every teacher in some way must automatically be teaching critical thinking.

Surely, we must mean more than “pedagogical content knowledge” (a favorite phrase of educator Lee Schulman); otherwise critical thinking would be a trivial phrase. And our colleagues cannot be accused of pursuing trivial chimeras, can they? So, this leads me to think about process. Critical thinking must have something to do with the way we think—the way we go about problem solving and asking questions. But I struggle with this, too.

More than a Mind-Set

I am currently a consultant to a drug company, even though I know little about the pharmaceutical business, except what I read in Reader’s Digest and on the back of pill bottles. The company has asked me to develop case studies to help their employees acquire a “drug hunter mind-set.” After long discussions, the only thing I can get out of this phrase is the obvious point—they want a streamlined way to avoid all of the pitfalls and cost of going off in the wrong direction as they search the pharmacopoeia for miracle cures for aging, baldness, cancer, impotence, sleepwalking, and mean-spiritedness.

I have not found any magic wand to do this; if it existed, others would have been there long ago. But I do believe there are better ways to solve problems—by developing habits of mind that speed things along. They include problem solving, skepticism, flexibility, and seeing alternative strategies when others see only one way.

Let’s take problem solving. Once again, this seems tied to specific content. I know that there are problem-solving exercises some authorities recommend—the “thinking out of the box” thing—but I don’t know of any evidence to support that they improve one’s approach to problems. Maybe the data exist, but I don’t know of any. It is hard to imagine that working crossword puzzles, reading Ann Landers’ opinions about personal crises, or letting your inner child out to play with finger paints helps you achieve...
Asking to see the evidence is a good forth. And it goes for supposed ex-
equipment, vitamin therapy, and so

lic about UFOs, psychic healing, as-

evidence, dominated the debate.

assumptions and hearsay, rather than
like it—over the war in Iraq. As-
be well off. Certainly, this is true in
your own area of expertise, you will
routinely ask such questions, even
mean when you say this?” If you

If I had to choose one general
characteristic that cuts across smart
people it would be skepticism—the
ability to ask oneself and others if
the conclusions and data are correct.

Smart people silently or openly say,
“What is the evidence for this or
that idea? Why should I believe this?
Are there other explanations
for the data? Is there another way
to explain the data? What do you
mean when you say this?” If you
routinely ask such questions, even
when dealing with subjects out of
your own area of expertise, you will
be well off. Certainly, this is true in
the political arena. We have just had
a terrible brouhaha—fiasco, is more
like it—over the war in Iraq. As-
sumptions and hearsay, rather than
evidence, dominated the debate.

Would that we could imbue
skepticism into the American public
about UFOs, psychic healing, astro-
tology, creation “science,” and a
host of other paranormal claims.
This goes for TV infomercials tout-
ing hair replacements, exercise
equipment, vitamin therapy, and so
forth. And it goes for supposed ex-
perts in our own disciplines as well.
Asking to see the evidence is a good

thing. It helps if you have a little
background in statistics too!

Now, how can we develop this
habit of mind in our students? The
best way is to model it ourselves.

Constantly, in lectures and discus-
sions, we should openly ask: “Why
should we believe this?” But this
isn’t enough. Most of us only got
good at this in our careers as gradu-
ate students. It happened as we
gained experience, read original lit-

ture, and attended journal clubs

If reading, arguing, and

of critical thinking, then
case studies are the poster
children for the process.

where articles were repeatedly at-
tacked. Then we rose eagerly to the
challenge. Soon we were emulating
our mentors and sneering at claims
of authors and doubting everything.
There was probably even a stage
where we were apt to be hypercriti-
cal and see nothing of worth in even
excellent papers because of some
trivial transgression in procedure. If
this is scenario is correct, then skep-
ticism can be taught!

This brings me to case studies.
If reading, arguing, and challenging
are hallmarks of critical thinking,
then case studies are the poster
children for the process. Most of them
are discipline specific, certainly. But
they all grapple with the essence of
critical thinking—asking for evi-
dence—developing a habit of mind
that should permeate everyday life.

Many case studies deal with real so-
cial problems such as global warm-
ing, pollution, environmental degra-
dation, and medical problems. I like
the ones that deal with general pro-
blems: How to develop a dossier when
seeking a job. Does prayer help heal
the sick? Does acupuncture work?
Such cases can be used in many dif-
ferent disciplines because of their
general nature.

Best-Case Scenario

The best case technique that I know
is one called the “Interrupted Case
Method.” Readers can see a version
of it on the National Center for Case
Study Teaching in Science website,
titled “Mom Always Liked You
Best.” The method begins when the
teacher gives students (ideally
working in groups) a problem faced
by real researchers. He asks the
students to come up with a tentative
approach to solving the problem.

After students work for about 15
minutes, the professor asks them to
report their thoughts. Then the

teacher provides some additional
information about the problem saying
that the real scientists who
struggled with the problem decided
to do it in a certain way.

The professor tells of additional
difficulties and asks students to brain-
storm solutions. Again, they report
after discussions. Then, perhaps the

teacher provides additional data for
their interpretation. Students consult
with their teammates and report out.
Again, the instructor gives them the
interpretation offered by the original
authors. And so on.

The interrupted case has enor-
mous virtues. Students struggle with
a real research problem and chal-

lenge each other and the data. Most
importantly, they see different
groups offering alternative ap-

proaches to the problem, and they

see model behavior from the experts.

I love this method because it is the
way real science works—we have to
work with incomplete data, make

tentative hypotheses, collect more
information, refine our hypotheses,
make more predictions, get more
data, and so on. In fact, this inter-
rupted method is the very one that I
use in workshops with the pharma-
ceutical industry, training folks there to attack problems. They like it, too.

So, I would argue that the case method has the real potential to develop the same skepticism that we all developed in graduate school when we analyzed research papers and saw what went on in the collection of data. The trouble with the lecture method is that it seldom exposes students to what really happens in the process of collecting data. Once students see this, they are forever changed. They rapidly recognize that there are alternative ways of attacking a problem and alternative interpretations of the data. They begin to doubt.

Most textbooks and lectures give purported facts as if they were received wisdom—wisdom that is certain and irrefutable. This is a great disservice. Students are not likely to question how we know a particular fact if we speak ex cathedra. We cannot develop a drug hunter mind-set this way, or any other type of inquiring mind.

William Perry, the Harvard psychologist famous for outlining the Perry model of student development, pointed out that the earliest stage in the maturity of students is the “dualist.” The dualist student sees the teacher and parents as absolute authority figures and everything in the textbook as correct. There are always right and wrong answers to questions. The job for these students is to learn that what teachers say is truth and regurgitate it back on the tests. The trouble with the lecture method is that it perpetuates this stage in students. Further, it distorts the actual way that science is accomplished. Students are left with the idea that Newton, sitting under an apple tree, was bonked on the head and gravity was born—it was all “eureka!”

Case studies don’t do this. They show the messy, get-the-hands-dirty approach that is the real science. Cases demand skepticism, flexibility, and the ability to see alternative approaches. Problem solving is its sine qua non. In short, cases demand critical thinking.
